

## INTERNAL BRIEFING

# The Qlix Platform

This document is for the Marketing and Content team. It explains what the Qlix platform is, why we built it, how each product fits together, and how to talk about it clearly to different audiences. No prior technical knowledge is assumed. Where technical terms are used, plain-English explanations follow.

## 01

## The Big Picture

*What is Qlix, and why does it exist?*

### What Is Qlix?

Qlix is a platform that lets organisations create, manage, and deploy intelligent AI agents — with identity and security built in from the ground up or bring your own agents onto our platform for identity and passport (explained later) services.

Think of it like an operating system for AI workers inside your organisation. Just as an operating system manages which programs run, what they can access, and who is allowed to use them — Qlix does the same for AI agents.

### The Problem We Are Solving

*Most AI platforms let you deploy agents first and try to secure them later. That creates four serious problems:*

- AI agents have no identity. When an AI takes an action, who did it? Without a verifiable identity, there is no accountability, no audit trail, and no way to know if an agent was tampered with.
- Access control is bolted on — not built in. Most platforms let you deploy AI first, then restrict what it does. This leads to over-privileged agents that can access far more than they should.
- Scaling agents means scaling risk. One AI agent is manageable. A hundred is a security nightmare. Without a structured system, permissions sprawl and nobody knows what is happening.
- Verification is missing at enrollment. How do you prove the person spinning up an agent is actually authorised to do so? Most platforms do not even ask the question.

**Our answer:** *Every Qlix agent has a verified identity, bounded permissions, and a traceable history — from the moment it is created.*

02

The Qlix Ecosystem

Four products, one platform

The Qlix platform is made up of four interconnected products. Understanding how they relate to each other is key to telling our story clearly.

Overview

| Product                | Type              | One-line description                                                                   |
|------------------------|-------------------|----------------------------------------------------------------------------------------|
| IRA                    | Desktop App       | The product your team uses day-to-day — chat with AI or spin up agents to handle work. |
| Passport               | Backend Service   | Gives every AI agent a verifiable cryptographic identity.                              |
| Agent Creation Service | Backend Service   | The secure pipeline that brings an agent to life, step by step.                        |
| ADK                    | Developer Toolkit | Build your own custom agents using our Agent Development Kit.                          |

03

IRA

The desktop app your users will actually touch

What Is IRA?

IRA is a fully-featured desktop application and the primary way users interact with the Qlix ecosystem. It is not a browser tab or a web app — it lives on your desktop and is always at hand.

IRA has two distinct modes:

Chat Mode

In Chat Mode, IRA functions like a powerful AI assistant. Users can have natural conversations, ask questions, draft documents, summarise information, in real time and ask questions on the content on your screen, and get help with day-to-day tasks — all from their desktop without switching to a browser.

- Conversational AI built directly into your desktop environment.
- Available instantly — no context switching, no browser tab to manage.

- Handles everyday requests: drafting, summarising, researching, explaining.

## Agent Mode

Agent Mode is where IRA connects to the full power of the Qlix platform. Rather than just answering a question, IRA can spin up a dedicated AI agent to handle a task autonomously — and it does so through a simple conversation.

- Describe a task in plain language and IRA creates an agent to handle it.
- Agents are created via Qlix's Agent Creation Service — securely, with a verified identity and bounded permissions (more on this in Section 04 and 05).
- Users can also create their own custom agents and configure them exactly as needed.

## Hosting Options

When a user creates or runs an agent through IRA, they have two hosting options:

**Run locally:** The agent runs entirely on the user's own machine. Useful for sensitive tasks that should never leave the device, or for offline use cases.

**Run on Qlix servers:** The agent is hosted and run on Qlix's own cloud infrastructure. This is the default option for most users and allows agents to run continuously without needing a local machine to be powered on.

**Marketing angle:** *IRA is how your team actually uses Qlix — a desktop app that makes spinning up AI agents as natural as sending a chat message.*

## 04

### Passport

*Every agent has a verified identity*

## What Is Passport?

Passport is the backend service that gives every AI agent on the Qlix platform a unique, cryptographic identity. Without Passport, an agent is just a piece of software with no name, no history, and no accountability.

With Passport, every agent is issued the equivalent of a digital ID card — one that cannot be faked, cannot be transferred, and can be verified by anyone, at any time.

## How It Works (in plain English)

- Every agent receives a unique identifier called a DID — a Decentralised Identifier. Think of it like a passport number that exists independently of any single system.
- The DID is generated using Ed25519 cryptography, which is the same technology used in military-grade security systems. It cannot be forged.
- Each agent is also issued a Verifiable Credential — a signed, tamper-proof document that describes what the agent is, who created it, which organisation it belongs to, and what it is allowed to do.
- Anyone — including external auditors — can verify an agent's identity via a public endpoint. No trust in a central authority is required.

## The Analogy

Think of a passport. A passport proves who a traveller is at a border. It is issued by a trusted authority, cannot be easily forged, and can be checked by anyone with the right tools. Passport does exactly this for AI agents — at every point where the agent takes an action inside your organisation.

**Marketing angle:** *Every Qlix agent carries a cryptographic ID. You always know exactly which agent did what — and so does every auditor.*

## 05

### Agent Creation Service

*The secure pipeline that brings agents to life*

## What Is the Agent Creation Service?

The Agent Creation Service is the backend process that runs whenever a new agent is created — whether through IRA's Agent Mode, or directly through the ADK, or through our simple 10 step questionnaire in our website. It is not a product users interact with directly; it is the set of enforced steps that make every agent trustworthy from the moment it exists.

Every step in the pipeline is mandatory. There are no shortcuts.

## The Five Steps

**Step 1 — Device Verified:** Before anything happens, the platform confirms that the request is coming from a trusted, authorised device. This prevents agents from being created by unknown or compromised machines.

**Step 2 — Organisation Check:** The platform confirms that the user creating the agent is a verified member of the relevant organisation. Agents cannot be created by users who do not belong to the right group.

**Step 3 — Scope Enforced:** The agent is granted only the minimum permissions it needs for its specific role — nothing more. This is what security professionals call the principle of least privilege.

**Step 4 — DID Generated:** The agent receives its unique cryptographic identity (see Passport, Section 04). This is the point at which the agent becomes a distinct, trackable entity.

**Step 5 — Verifiable Credential Issued:** The platform issues a signed, tamper-proof credential that attaches the agent's identity to its permissions, its creator, and its organisation. This credential travels with the agent and can be verified externally at any time.

**The result:** *A live, verified AI agent with a unique identity, bounded permissions, and a publicly verifiable credential — ready to work.*

## 06

### ADK

*Build your own agents — your way*

## What Is the ADK?

The ADK — Agent Development Kit — is Qlix's developer toolkit for teams and individuals who want to build their own custom AI agents from the ground up. Rather than using Qlix's web platform to create agents, developers use the ADK to write, configure, and deploy agents programmatically, but use our services for the identity and auditing.

Agents built with the ADK go through exactly the same Agent Creation Service pipeline as any other Qlix agent. They receive a Passport identity, have their permissions scoped, and are fully verified. The ADK is simply a different entry point into the same secure system.

## Who Is It For?

- Developers who want to build purpose-built agents for specific workflows or products.
- Teams who want to customise agent behaviour far beyond what is possible through Qlix's interface.
- Organisations who want to integrate Qlix-verified agents into their own internal tools and systems.

## What Can You Build With It?

The ADK gives developers full control over their agent's behaviour, logic, and integrations. Examples include:

- A customer support agent trained on your specific product documentation.
- An internal research agent that monitors data sources and surfaces insights automatically.
- A workflow automation agent that handles multi-step processes across different tools.
- A code review agent that checks pull requests against your team's standards.

## Hosting Options for ADK Agents

Agents built with the ADK have the same two hosting options as agents created through IRA:

**Host locally:** Run the agent on your own infrastructure. You retain full control over compute, data, and uptime. Ideal for sensitive workloads or teams with strict data residency requirements.

**Host on Qlix Cloud:** Deploy the agent to Qlix's own servers. Qlix manages uptime, scaling, and infrastructure. The agent runs continuously and is accessible without needing a local machine online. This is the fastest route to production for most teams.

**Marketing angle:** *Whether your team is a solo developer, a normal user who wants to use ai agents or an engineering department, the ADK lets you build exactly the agent you need — and deploy it with the same trust and security guarantees as any other Qlix product.*

## 07

### Security Architecture

*How the platform enforces trust at every layer*

You do not need to memorise the cryptography. But understanding the three security layers helps you explain our security story — and answer questions from technically-minded audiences.

## Layer 1 — Session Security

**Tech:** JWT Cookie

**Plain English:** Your everyday login. A short-lived web token that proves you are a valid, authenticated user. Like a wristband at an event — it is valid until it expires, then you refresh it. This applies to all standard interactions with the platform.

## Layer 2 — Step-Up Security

**Tech:** WebAuthn + Short-Lived Token

**Plain English:** Your biometric. Before any sensitive action, the platform asks for a fingerprint or face scan via your device. The resulting token is valid for only a few minutes. This is not optional — there is no way to bypass it for protected operations.

## Layer 3 — Enrollment Security

**Tech:** Passkey Verification

**Plain English:** Your hardware key. The final check during agent creation. Your passkey — a credential physically tied to your device — confirms that you are not just logged in, but that you physically hold the authorised device. This makes it effectively impossible to create an agent remotely or without physical access to the right machine.

**For security audiences:** Qlix uses a three-layer auth model — session JWT, WebAuthn step-up, and passkey enrollment — combined with Ed25519 DIDs and platform-signed Verifiable Credentials. IRA is the client; Qlix handles the security layer.

## 08

### Messaging Guide

*How to talk about Qlix to different audiences*

The way you describe Qlix should change depending on who you are speaking to. The facts stay the same — but the emphasis shifts significantly.

## General Audience

**Say:** *IRA is a desktop app where you chat with AI or spin up AI agents to handle your work — backed by Qlix's identity and security infrastructure. If you want to build your own custom agent, the ADK gives you the tools to do it.*

- Avoid:
  - Do not lead with 'Qlix platform' — lead with IRA as the product they will actually touch and use daily.
  - Do not use terms like DID, WebAuthn, or Ed25519. Explain the outcome, not the technology.

## Security and IT Audiences

**Say:** Qlix provides the backend: Ed25519 DIDs, WebAuthn step-up auth, passkey enrollment, and platform-signed Verifiable Credentials. IRA is the client that plugs into it. Agents built with the ADK go through the same identity pipeline — local or cloud-hosted.

- Do go technical here — they want specifics and will distrust vague claims.
- Emphasise that the security model is enforced at the infrastructure level, not bolted on after deployment.

## Executive and Decision-Maker Audiences

**Say:** IRA gives your team an AI assistant on their desktop. When they need an agent for a bigger task, it spins one up through Qlix — automatically governed and traceable. Developers can also build custom agents with our ADK, and host them on our cloud or their own infrastructure.

- Skip the architecture. Lead with business value: compliance, auditability, speed, and developer flexibility.
- Emphasise that your team gets a powerful tool and your security team retains full control.

## Developer Audiences

**Say:** The ADK gives you full control over your agent's logic, integrations, and behaviour — with Qlix handling identity, verification, and security under the hood. Deploy locally or to Qlix Cloud.

- Lead with capability and flexibility, not compliance.
- Emphasise that Qlix security does not slow down development — it is automatic.

---

# The Qlix Promise

*Every agent, verified. Every action, bounded. Every identity, provable.*

IRA is what your team uses. Passport is what makes every agent trustworthy. The Agent Creation Service is what makes the process airtight. And the ADK is what gives developers the freedom to build exactly what they need — on their terms, with our guarantees.

.
